ANTIMICROBIAL AND CLINICAL MICROBIOLOGY GUIDEBOOK

Eighth edition

January 2022

TABLE OF CONTENTS

ANTIMICROBIAL AND CLINICAL MICROBIOLOGY GUIDEBOOK

2022

INTRODUCTION

This is the Eighth Edition of the Antimicrobial and Clinical Microbiology Guidebook at Lawrence Memorial Hospital. The development of this guidebook has been a joint effort of the Antimicrobial Stewardship Program, Infectious Disease and Prevention, Pulmonology Specialist Group, Pharmacy, and the Microbiology Department. The purpose of the booklet is to optimize antimicrobial usage and patient outcomes for infectious disease-related issues.

Every effort has been made to ensure that the information is complete, accurate, and up to date; however, this booklet does not serve as a substitute for clinical judgment or consultation with experts in Infectious Diseases. Application of this information to each clinical situation is the responsibility of the practitioner.

Contributors

Megan Germer, PharmD

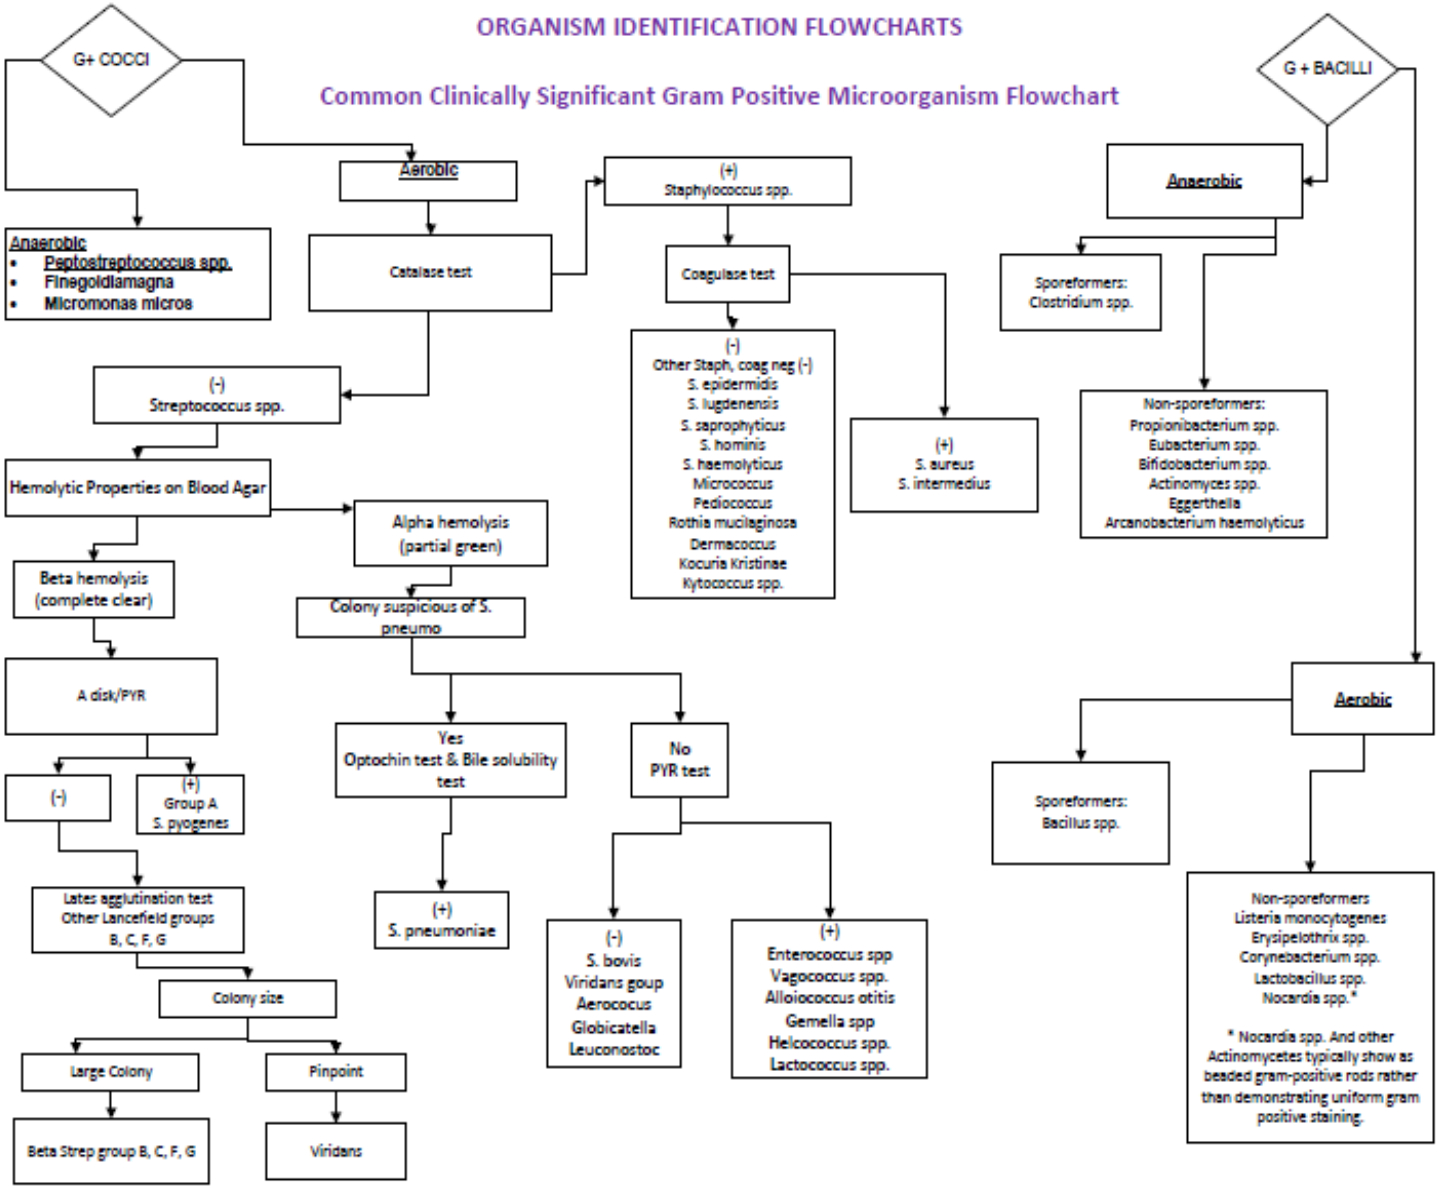
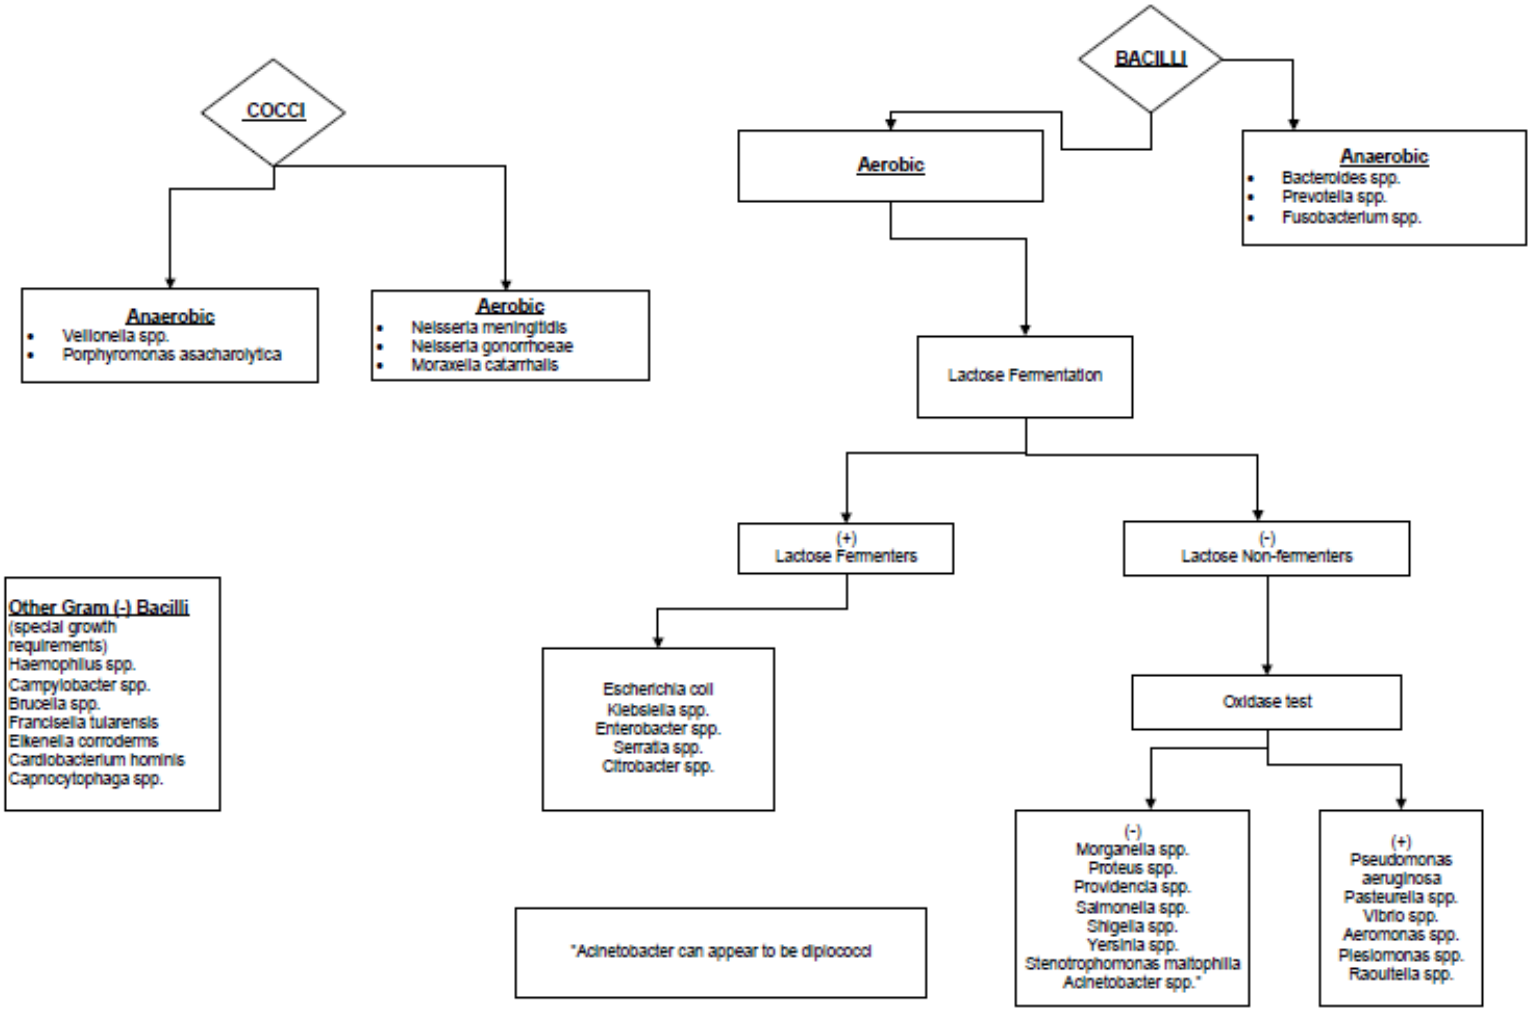
ORGANISM IDENTIFICATION FLOWCHARTS

Common Clinically Significant Gram Positive Microorganism Flowchart



ORGANISM IDENTIFICATION FLOWCHART

Common Clinically Significant Gram Negative Microorganism Flowchart



Key phrases from the Microbiology Laboratory

Phrase	Suggested findings
Gram positive cocci in clusters	*Staphylococcus* species
Gram positive cocci in pairs and chains	*Streptococcus* species or *Enteroccoccus* species
Gram positive cocci in pairs	*Streptococcus pneumoniae*
Small pleomorphic Gram negative coccobacilli	*Haemophilus* species
Pleomorphic Gram positive bacilli	*Corynebacterium* species or *Cutibacterium (prev. Propionobacterium) species*
Branching Gram positive bacilli	*Actinomyces* or *Nocardia* species
Acid fast bacilli	*Mycobacterium* species
Budding yeast or pseudohyphae	yeast
Fungal elements or hyphal elements	mold
Gram negative fusiform bacilli	*Fusobacterium* species or *Capnocytophaga species*

BACTERIOLOGY

Susceptibility Testing

Susceptibility testing is an *in vitro* assay that allows us to detect resistance to antimicrobial agents that may be used to treat an infection. It is important to note however, that clinical outcome may be dependent on various patient specific factors such as immune status or surgical treatment that are not reflected in laboratory tests.

All methods of susceptibility testing are based on diffusion or dilution.

A. Semi-Automated Susceptibility Testing

Semi-automated antimicrobial susceptibility testing is performed using the Vitek 2 system which is based on broth microdilution. This system allows the laboratory to rapidly perform identification and susceptibility testing on most common pathogens (e.g. Staphylococci, Enterobacteriaceae, Enterococci, *Pseudomonas* species, etc…). The antibiotics tested vary based upon the Vitek panel used and the antibiotics that are currently on the LMH formulary. The Vitek panels are chosen and agreed upon by the Antimicrobial Stewardship Committee, Pharmacy, Infectious Disease Physicians, and the microbiology laboratory.

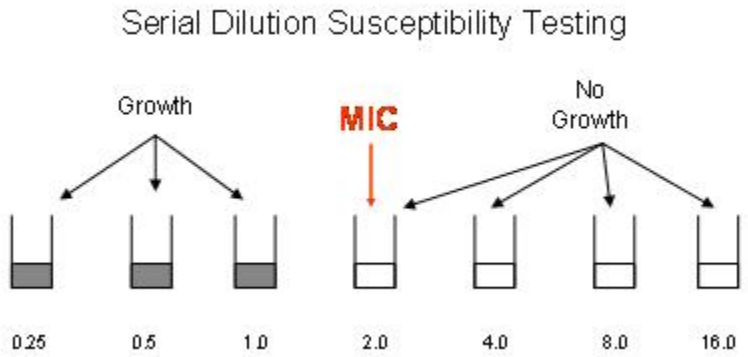
The microbiology laboratory reports antibiotics from most antibiotic classes that are appropriate for the specific organism tested. For example, if the laboratory recovers an isolate from urine, the results from the following antibiotic classes are reported: penicillin, Beta lactam/Beta lactamase combination, cephems, carbapenems, aminoglycosides, fluoroquinolones, nitrofurantoin, and trimethoprim-sulfamethoxazole.

Selective reporting of antibiotics for each organism group is reviewed and approved by the Antimicrobial Stewardship Committee and the medical director of the laboratory annually.

The results obtained from the Vitek system are based on the minimum inhibitory concentration (MIC). The MIC is defined as the lowest concentration of antibiotic that completely inhibits growth of the specific organism being tested.

For example, in figure 1 below, the organism being tested grew in wells containing 0.25, 0.5, and 1.0 ug/ml of antibiotic. The lowest concentration of antibiotic (MIC) that completely inhibits growth was 2.0 ug/ml.

Figure 1:



(http://vads.vetmed.vt.edu/Images/SerialDilutionSusceptibility.jpg)

The MIC is then interpreted (S=susceptibile, I=Intermediate, or R=resistant) using FDA approved guidelines. These guidelines are based on many studies, including clinical, pharmacokinetic/pharmacodynamic, and microbiological studies.

It is important to be aware that, although there are many examples of bacteria and antibiotics for which we have FDA approved guidelines for reporting of automated susceptibility results, there are some bacteria for which FDA approved guidelines do not exist. If susceptibility testing for a specific organism cannot be reported using the automated Vitek method, disc diffusion testing may be performed and results will be reported based on CLSI (Clinical and Laboratory Standards Institute) standards if available.

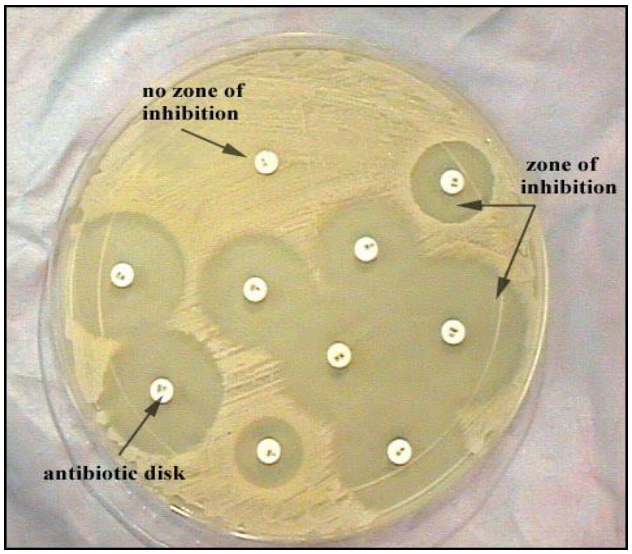
If the laboratory cannot perform testing in-house, the physician may notify the microbiology laboratory (505-6177) and request the isolate be submitted to a reference laboratory for further testing.

B. Disk Diffusion

The LMH microbiology laboratory does routinely perform disk diffusion (Kirby Bauer) antimicrobial susceptibility testing for *Pseudomonas aeruginosa* isolates from cystic fibrosis

patients, beta-lactamase positive *Haemophilus* species, and other fastidious organisms. Disk diffusion allows for measurement of the zone of growth inhibition. See figure 2.

Figure 2:



(http://mrsa30day.com/wp-content/uploads/2012/08/Antibiotic-sensitivity.jpg)

The CLSI provides interpretive standards for reporting an organism as S, I, or R based on the zone of inhibition. The main difference between disk diffusion testing and MIC testing is that disk diffusion provides clinicians with qualitative results, whereas MIC testing provides the clinicians quantitative results.

Knowing the MIC can help clinicians incorporate pharmacodynamic/pharmacokinetic principles into the design of the treatment regimen. For instance, if the clinician wants to use ceftriaxone to treat meningitis due to *Streptococcus pneumoniae*, we need to achieve a concentration in the cerebrospinal fluid (CSF) of approximately four times the MIC for about 40% of the dosing interval due to the time-dependent/concentration-independent nature of the drug. Therefore, if the MIC of the *S. pneumoniae* isolate to ceftriaxone is 0.25 ug/ml, we want a concentration of at least 1 ug/ml in the CSF for 40% of the dosing interval.

The size of the zone of inhibition does not give us the MIC, and so in this specific case disk diffusion is not helpful. Also, zone sizes cannot be compared between drugs. Just because drug A has a larger zone size than drug B, it does not mean that drug A will work better. Zone sizes must be correlated back to the CLSI interpretive standards in order to determine susceptibility or resistance.

C. E-test

The LMH laboratory does perform E-test susceptibility testing for daptomycin on all MRSA and VRE isolates from non-respiratory tract sites per the Infectious Disease practitioner. Daptomycin susceptibility testing is available by E-test upon special request by ID or

Pharmacy. Penicillin susceptibility testing is also available by E-test for unusual Strep species.

The E-test is an agar based method that uses a plastic strip with antibiotic concentrations in variable size plastic disks on its underside. When placed on an agar surface pre-inoculated with the bacterial isolate, the diffusing antibiotic creates a concentration gradient in the agar. Decreasing concentrations of antibiotic from the top of the strip to the bottom create an ellipsoid diffusion pattern around the strip. The resultant elliptical zone of inhibition allows the MIC to be read at the point where the zone crosses the E-test strip (figure 3).

Figure 3:

D. Special Susceptibility Testing Issues:

Extended-spectrum Beta-lactamases (ESBL's)

ESBL's are Beta-lactamases that are capable of hydrolyzing expanded-spectrum cephalosporins (ceftriaxone, cefotaxime, and ceftazidime) as well as cefepime and aztreonam. ESBL's can be isolated from many different Enterobacteriaceae species but are most commonly isolated from *Klebsiella pneumoniae*, *Klebsiella oxytoca*, *E. coli*, and *Proteus mirabilis*.

Using the Vitek, isolates that carry ESBL's can initially be intermediate or resistant to one or all of the extended spectrum cephalosporins, cefepime or aztreonam. This is due to the fact that there are many different ESBL's with different substrate specificities. The Vitek gram negative panel includes an ESBL confirmatory test and all ESBL positive isolates are verified. If a particular isolate is confirmed as resistant or intermediate to any of the extended-spectrum cephalosporins, cefepime or aztreonam, the following statement will be included in the report: "Isolate is an ESBL producing strain resistant to all penicillins, cephalosporins, and aztreonam."

ESBL positive *E coli* isolates from urinary tract specimens will be tested for fosfomycin susceptibility per the Antimicrobial Stewardship Committee.

The GenMark Gram Negative Blood culture assay can detect the CTX-M beta-lactamase resistance mechanism. CTX-M is a beta-lactamase that has potent activity against cefotaxime. The mechanism of resistance is plasmid-mediated.

Because of the significant public health implications, the spread of CTX-M beta-lactamase producers' merits close monitoring.

Carbapenemases:
Carbapenemases are beta-lactamases that are capable of hydrolyzing all beta-lactams, including the carbapenems. Carbapenemases can be isolated from many different Enterobacteriaceae species.

Carbapenemases are particularly dangerous resistance mechanisms, since they can inactivate a wide range of different antibiotics. Enterobacteriaceae, Pseudomonas, and Acinetobacter isolates that produce carbapenemase have been referred to as "Infection Control Emergencies." Bacteria that produce carbapenemases (carbapenemase-producing-Carbapenem resistant organisms, ie. CP-CRO) are often referred to in the news as "superbugs" because infections caused by them are extremely difficult to treat.

For all acute care facilities, CDC and HICPAC recommend an aggressive infection control strategy, including managing all patients with carbapenem resistant organisms (CRO) and carbapenemase producing-carbapenem resistant organisms (CP-CRO) using contact precautions.

There are several important mechanisms of carbapenemase producing carbapenem resistance that increases the risk for dissemination:

1. KPC: *Klebsiella pneumoniae* carbapenemase (KPC) refers to the production of a carbapenemase enzyme, bla_{kpc}. The gene that encodes the bla_{kpc} enzyme is carried on a mobile piece of genetic material (transposon), which can easily be passed from one organism to the other.

2. NDM: New Dehli Metallo-beta-lactamase-1 refers to the production of a carbapenemase referred to as NDM-1 enzyme. The most common bacteria that produce this enzyme are gram negatives such as *E coli* and *Klebsiella pneumoniae,* but the gene for NDM bla_{NDM-1} can spread from one strain of bacteria to another by horizontal gene transfer.

3. IMP: IMP-type carbapenemases are plasmid mediated Class B metallo-beta-lactamases that can be found in both enteric Gram-negative organisms and in *Pseudomonas* and *Acinetobacter* species.

4. VIM (Verona integron-encoded metallo-beta-lactamase): The VIM family of carbapenemases occur mostly in *Pseudomonas aeruginosa* and *P. putica* and vary rarely in Enterobacteriaceae. The VIM enzymes are integron-associated and hydrolyse all beta-lactams and can evade all beta-lactam inhibitors.

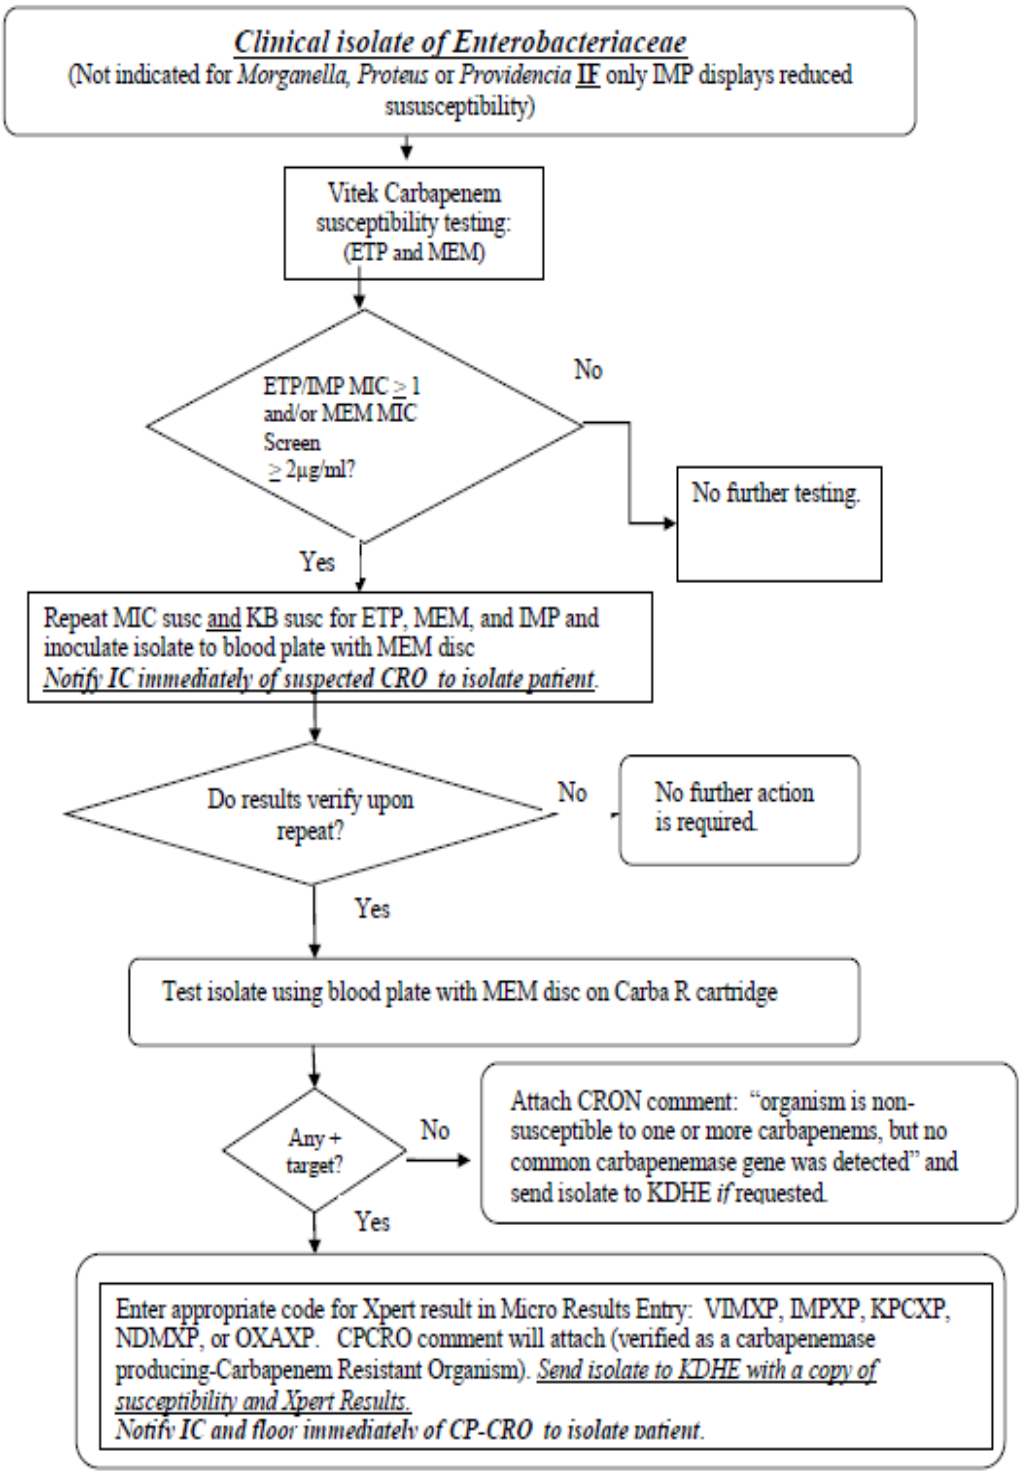
5. OXA (Oxacillinase): The OXA group of beta-lactamases occur mainly in Acinetobacter species.

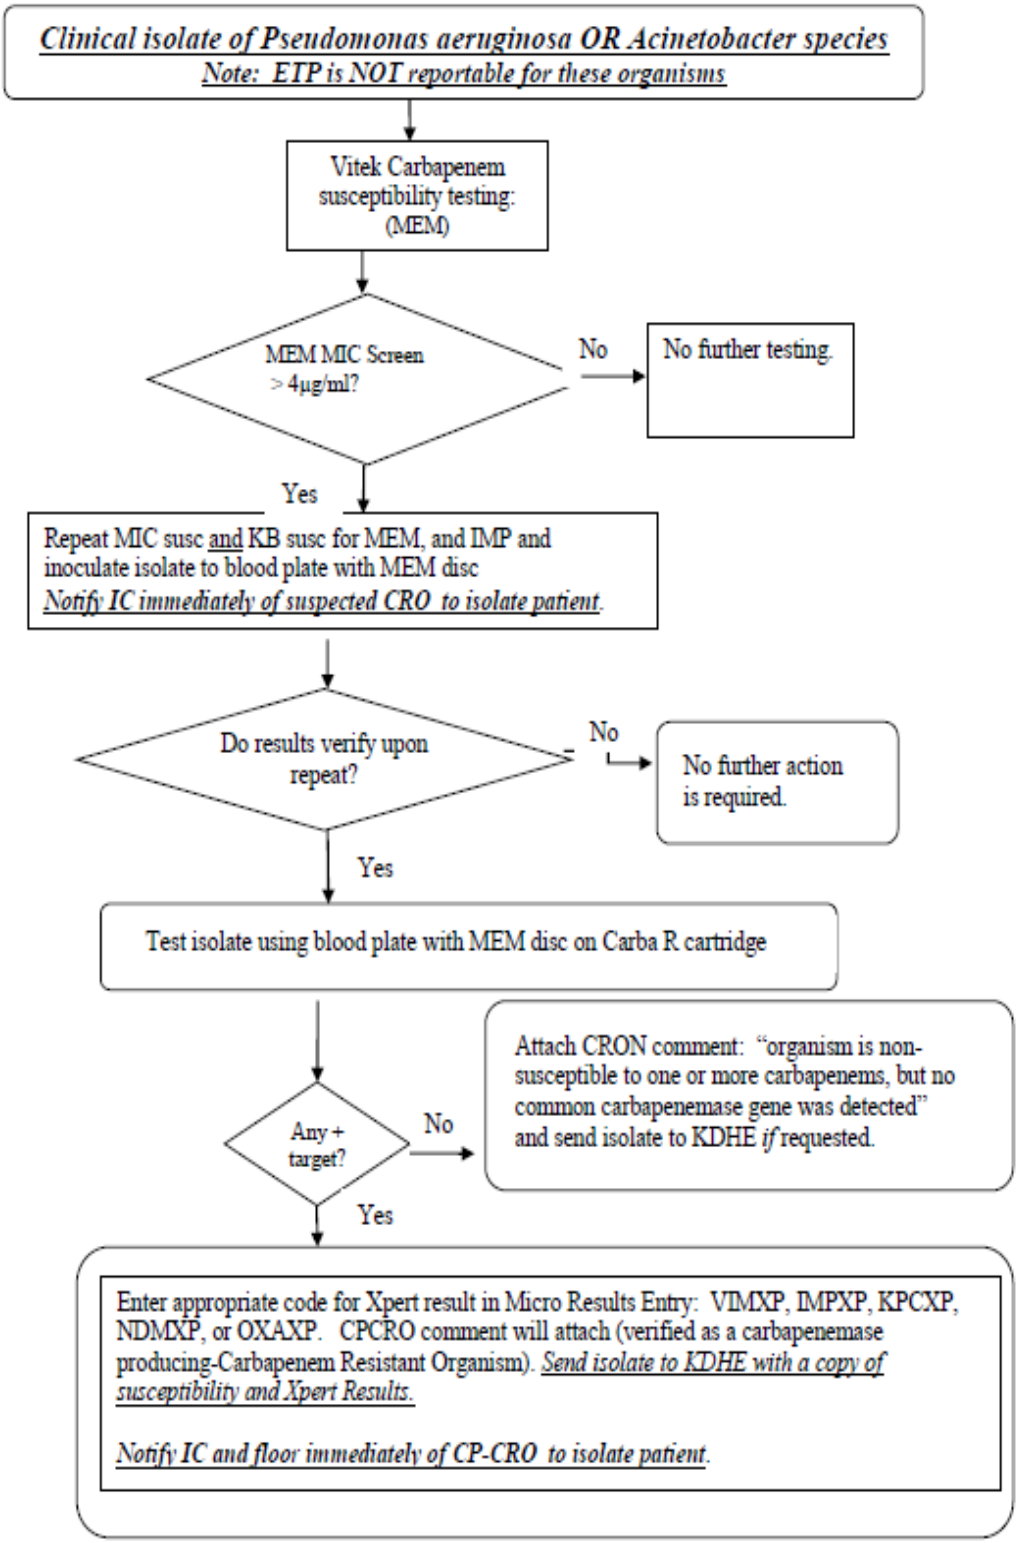
The GenMark Gram Negative Blood Culture assay can detect the following carbapenem resistance mechanisms in positive blood cultures: KPC, NDM, VIM, OXA, and IMP. Infectious disease consultation is suggested when one of these resistance mechanisms is detected.

If the Vitek susceptibility profile suggests the presence of a carbapenemase producing organism, the microbiology department will repeat testing and will also perform Kirby bauer susceptibility testing for Avycaz (Ceftazidime/Avibactam). In addition, the lab will perform a Carba-R test on the Gene Xpert on the isolate. The Carba-R cartridge can detect KPC, NDM, VIM, OXA, and IMP. The following flowcharts were developed for testing based on CDC recommendations.

It is important to note that if an isolate is suspected to be a carbapenemase producing carbapenem resistant organisms (CP-CRO), the Infectious Disease specialist and the Infection Preventionist will be notified immediately to ensure the patient is placed in isolation. Carbapenemase screening can be performed if ordered by Infection Prevention. A rectal swab (dual swab culturette with Liquid Stuart's media) should be collected for screening.

Practical Testing Schemes to Carbapenemase Producing-Carbapenem Resistant Organism (CP-CRO) vs. Carbapenem Resistant Organism (CRO) Using the Xpert Carba-R Cartridge





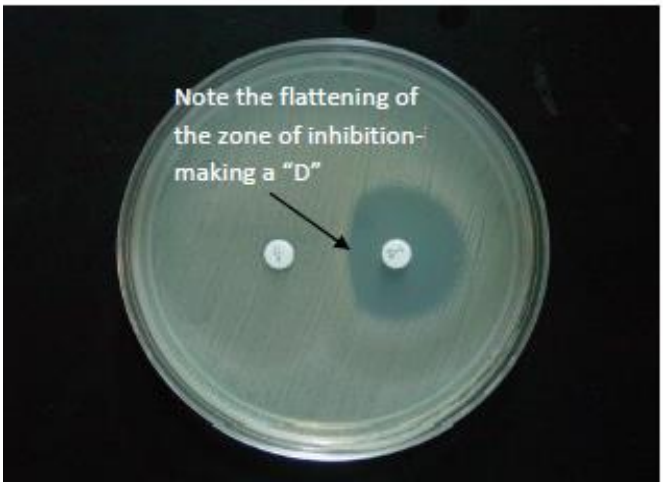
Clinical isolate of Pseudomonas aeruginosa OR Acinetobacter species
Note: ETP is NOT reportable for these organisms
Vitek Carbapenem susceptibility testing: (MEM)
MEM MIC Screen > 4µg/ml?
No
No further testing.
Yes
Repeat MIC susc and KB susc for MEM, and IMP and inoculate isolate to blood plate with MEM disc
Notify IC immediately of suspected CRO to isolate patient.
Do results verify upon repeat?
No
No further action is required.
Yes
Test isolate using blood plate with MEM disc on Carba R cartridge
Any + target?
No
Attach CRON comment: "organism is non-susceptible to one or more carbapenems, but no common carbapenemase gene was detected" and send isolate to KDHE if requested.
Yes
Enter appropriate code for Xpert result in Micro Results Entry: VIMXP, IMPXP, KPCXP, NDMXP, or OXAXP. CPCRO comment will attach (verified as a carbapenemase producing-Carbapenem Resistant Organism). Send isolate to KDHE with a copy of susceptibility and Xpert Results.
Notify IC and floor immediately of CP-CRO to isolate patient.

Inducible clindamycin-resistance in *Staphylococcus* and *Streptococcus* species:
Erythromycin resistance within staphylococci is typically mediated through two distinct mechanisms. The first mechanism entails protection of the ribosome from erythromycin and clindamycin through methylation (referred to as MLS_B resistance). This mechanism may be constitutive (conferring resistance to both erythromycin and clindamycin) or inducible (conferring resistance only to erythromycin). Published clinical reports have demonstrated that *S. aureus* isolates carrying an inducible MLS_B resistance gene should be considered resistant to clindamycin even if the *in vitro* result considers the isolate susceptible to clindamycin. The second resistance mechanism is conferred through efflux of erythromycin out of the cell through specific pumps (encoded by the msrA gene). Staphylococcal isolates carrying the MsrA efflux pump are resistant only to erythromycin and not clindamycin.

The Vitek performs an inducible clindamycin resistance (ICR) test (otherwise known as D-test) automatically on *Staph* species, group A Beta *Strep* and group B Beta *Strep*. If the test is positive for ICR, the clindamycin result is not reported and a comment is attached to the report "isolate presumed resistant to clindamycin by ICR testing."

Isolates of *Streptococcus pneumoniae,* and other Beta *Streptococcus* species (as specified by CLSI) may require a manual D-test performed (Figure 4). If the D-test is positive the clindamycin result is not reported and a comment is attached to the report "isolate presumed resistant to clindamycin by ICR testing."

Figure 4
(positive D-test by manual method):



Inducible Methicillin Resistance in Staph aureus:

Methicillin resistance in *S. aureus* is generally due to the presence of the *mecA* gene located on the staphylococcal cassette chromosome *mec*(SCC*mec*). The *mecA* gene codes for production of an altered penicillin binding protein PBP2', also referred to as PBP2a. PBP2' has a low binding affinity for beta-lactam antibiotics. Because oxacillin and other beta-lactams cannot bind to the altered PBP2' site, these antibiotics are ineffective. The 'gold standard' for the detection of MRSA is molecular methodology using either polymerase chain reactions (PCR) or nucleic acid amplification. Molecular methods for detection of genes such as *mecA* that code for resistance are being used in laboratories with increasing frequency. However, routine susceptibility testing by microdilution or disk diffusion is still the method of choice for resistance determination in most laboratories.

Until recently, our laboratory used microdilution and PBP2' latex methods to detect MRSA. In January 2012, the Cepheid SSTI MRSA/MSSA cartridge for use on the GeneXpert platform was added to the laboratory's test menu. In addition to a routine wound culture, we began to offer a special site culture with PCR for MRSA/MSSA. PCR results are available in just over one hour from the time of specimen receipt in the laboratory. PCR testing performed on these specimens is followed up with routine culture and susceptibility testing.

Our laboratory has previously identified *S aureus* isolates from outpatient wound specimens that were positive for the *mec*A gene by PCR that were found to be sensitive to oxacillin by follow-up routine susceptibility testing. Upon further investigation, these isolates were found to demonstrate resistance in vitro, after exposure to a beta-lactam (cefoxitin) antibiotic. In other words, the *S aureus* isolates demonstrated "inducible methicillin resistance."

The prevalence of this inducible methicillin resistant *S aureus* strain (Ridom spa type T175) has been found to be low however susceptibility testing alone can miss these strains. It is important to be aware that this strain has historically been found in our community. Also, it is important to note that if an inducible MRSA isolate were isolated from a serious infection, such as sepsis, and the infection were treated with first-generation cephalosporins or semi-synthetic penicillin, the patient may fail therapy.

INTRINSIC RESISTANCE TABLES

Intrinsic resistance is the innate ability of a bacterial species to resist activity of a particular antimicrobial agent through its inherent structural or functional characteristics. Such natural resistance can be due to: lack of affinity of the drug for the bacterial target, inaccessibility of the drug into the bacterial cell, extrusion of the drug by chromosomally encoded active exporters, or innate production of enzymes that inactivate the drug.

Below are lists of organisms with their respective intrinsic antimicrobial resistance.

Enterococcus species	Antimicrobial agents								
Organisms	Cephalosporins	Vancomycin	Teicoplanin	Aminoglycosides	Clindamycin	Quinupristin-dalfopristin	Trimethoprim	Trimethoprim/Sulfamethoxazole	Fusidic Acid
Enterococcus faecalis	R*			R*	R*	R	R	R*	R
Enterococcus faecium	R*			R*	R*		R	R*	R
Enterococcus gallinarum/ Enterococcus casseliflavus	R*	R		R*	R*	R	R	R*	R

*Warning: For *Enterococcus* spp., cephalosporins, aminoglycosides (except for high level resistance screening), clindamycin, and trimethoprim-sulfamethoxazole may appear active in vitro, but are not effective clinically.

Note: Gram-positive bacteria are also intrinsically resistant to aztreonam, polymyxin B/colistin and naladixic acid.

Staphylococci	Antimicrobial Agents		
Organisms	Novobiocin	Fosfomycin	Fusidic Acid
S. aureus	There is no intrinsic resistance in these species.		
S. lugdenensis			
S. epidermidis			
S. haemolyticus			
S. saprophyticus	R	R	R
S. capitis		R	
S. cohnii	R		
S. xylosus	R		

Notes:

1. Gram positive bacteria are also intrinsically resistant to aztreonam, polymyxin B/colistin and naladixic acid.
2. MRSA and oxacillin resistant coagulase negative staphylococci are considered resistant to other beta-lactam agents, (penicillins, beta-lactam/beta-lactamase inhibitor combinations, cephems with the exception of ceftaroline), and carbapenems.

Enterobacterales	**Antimicrobial Agent**											
Organisms	Ampicillin	Amoxicillin-clavulanic acid	Ampicillin-sulbactam		Ticarcillin	Cephalosporin I: Cefazolin, Cephalothin	Cephamycins: Cefoxitin, Cefotetan	Cephalosporin II: Cefuroxime	Imipenem	Tetracyclines and Tigecycline	Nitrofurantoin	Polymyxin B/Colistin
Citrobacter freundii	R	R	R			R	R	R				
Citrobacter koseri	R				R							
Klebsiella aerogenes (prev.Enterobacter)	R	R	R			R	R	R				
Enterobacter cloacae complex	R	R	R			R	R	R				
Escherichia coli	There is no intrinsic resistance to beta-lactams in this organism											
Escherichia hermannii	R				R							
Hafnia alvei	R	R	R			R	R					
Klebsiella pneumoniae	R				R							
Morganella morganii	R	R				R		R	*	R	R	R
Proteus mirabilis	No intrinsic resistance to penicillins and cephalosporins								*	R	R	R
Proteus penneri	R					R		R	*	R	R	R
Proteus vulgaris	R					R		R	*	R	R	R
Providencia rettgeri	R	R				R			*	R	R	R
Providencia stuartii	R	R				R				R	R	R
Salmonella* and *Shigella spp	No intrinsic resistance to beta-lactams in these organisms 1ST AND 2ND generation cephalosporins may appear active in vitro, but are not effective clinically.											
Serratia marcescens	R	R	R			R	R	R			R	R
Yersinia enterocolitica	R	R			R	R						

Note: Cephalosporins III, cefepime, aztreonam, ticarcillin-clavulanate, piperacillin-tazobactam, and the carbapenems are not listed, because there is no intrinsic resistance in Enterobacteiaceae.

Enterobacteriaceae are also intrinsically resistant to clindamycin, daptomycin, glycopeptides, (vancomycin), linezolid, macrolides (erythromycin, clarithromycin, azithromycin), quinupristin-dalfopristin, and rifampin.

Non-Enterobacteriaceae	Antimicrobial Agents																				
Organisms	Piperacillin	Ticarcillin	Ampicillin-Sublactam	Amoxicillin-clavulanic	Piperacillin-tazobactam	Ampicillin, Amoxicillin	Cefotaxime	Ceftriaxone	Ceftazidime	Cefepime	Aztreonam	Imipenem	Meropenem	Ertapemem	Polymyxin B/Colistin	Aminoglycosides	Tetracycline	Tigecycline	Trimethoprim	Trimethoprim/Sulfa	Chloramphenicol	Fosfomycin
Acinetobacter baumannii/ A. calcoaceticus complex			*	R		R					R			R					R		R	R
Burkholderia cepacia complex	R	R	R	R	R	R	R	R		R	R	R		R	R	R			R			R
Pseudomonas aeruginosa			R	R		R	R	R						R			R	R	R	R	R	R
Steno. maltophilia	R	R	R	R	R	R	R	R			R	R	R	R		R	#	#	R			R

1. **Acinetobacter baumannii/calcoaceticus* may appear to be susceptible to ampicillin-sulbactam due to the activity of sulbactam with this species.
2. # *Stenotrophomonas maltophilia* is intrinsically resistant to tetracycline but not to doxycycline or minocycline.
3. Note: Nonfermentative gram-negtive bacteria are also intrinsically resistant to cephalosporin I (cephalothin, cefazolin), cephalosporin II (cefuroxime), cephamycins (cefoxitin, cefotetan), clindamycin, daptomycin, fusidic acid, glycopeptides (vancomycin, teicoplanin), linezolid, macrolides (erythromycin, azithromycin, clarithromycin), penicillin, quinupristin-dalfopristin, and rifampin.

Other organisms:

Organisms	Natural Resistance Against
Anaerobic bacteria	Aminoglycosides
Aerobic bacteria	Metronidazole
Lactobacilli and *Leuconostoc*	Vancomycin
Aerococcus urinae	Sulfonamides and Netilmicin
Cardiobacterium hominis	Clindamycin

Footnotes

a. Data were generated from unique isolates from patient specimens submitted to Tufts Medical Center, Boston, Massachusetts; International Health Management Associates, Inc., Schaumburg, Illinois; R.M. Alden Research Laboratory, Culver City, California; Creighton University School of Medicine, Omaha, Nebraska; Mayo Clinic College of Medicine and Science, Rochester, Minnesota; and the Centers for Disease Control and Prevention, Atlanta, Georgia. All testing was performed by the agar dilution method. Information and analysis of previous versions of this table have been published.

b. Intermediate category is not shown but can be derived by subtraction of %S and %R for each antimicrobial agent from %100.

c. Calculated from fewer than the CLSI document M39[1] recommendation of 30 isolates.

C. perfringens	425	83	12	23[c]	83[c]	9[c]	425	100	0
Clostridioides (formerly *Clostridium*) *difficile*[g]	1013	32	38	480	74	25	1343	100	0
Other *Clostridium* spp.	461	67	25	71	62	35	461	100	0

Footnotes

a. Data were generated from unique isolates from patient specimens submitted to Tufts Medical Center, Boston, Massachusetts; International Health Management Associates, Inc., Schaumburg, Illinois; R.M. Alden Research Laboratory, Culver City, California; Creighton University School of Medicine, Omaha, Nebraska; Mayo Clinic College of Medicine and Science, Rochester, Minnesota; and the Centers for Disease Control and Prevention, Atlanta, Georgia. All testing was performed by the agar dilution method. Information and analysis of previous versions of this table have been published.

b. Intermediate category is not shown but can be derived by subtraction of %S and %R for each antimicrobial agent from %100.

c. Calculated from fewer than the CLSI document M39[1] recommendation of 30 isolates.

d. A dash (-) indicates that data were not available.

e. Anaerobic gram-positive cocci include *Peptococcus*, *Peptostreptococcus*, *Finegoldia*, *Peptoniphilus*, and *Anaerococcus* species.

f. 80 isolates of *Cutibacterium* (formerly *Propionibacterium*) *acnes* from two of the sites generated MIC values for rifampin ≤ 0.03 µg/mL using the agar dilution method. There are no interpretive breakpoints for this organism/antimicrobial agent combination.

g. *Clostridioides* (formerly *Clostridium*) *difficile* isolates are from an intestinal source; these results do not imply efficacy for intraluminal infections. Vancomycin minimal inhibitory concentrations for isolates were < 4 µg/mL.

Reference for D2

[1] CLSI. *Analysis and Presentation of Cumulative Antimicrobial Susceptibility Test Data; Approved Guideline—Fourth Edition.* CLSI document M39-A4. Wayne, PA: Clinical and Laboratory Standards Institute; 2014.

Development of Resistance and Testing of Repeat Isolates: Isolates that are initially susceptible may become intermediate or resistant after initiation of therapy. Therefore, subsequent isolates of the same species from a similar body site should be tested in order to detect resistance that may have developed. This can occur within as little as three to four days and has been noted most frequently in *Enterobacter, Citrobacter*, and *Serratia* spp. with third-generation cephalosporins; in *P. aeruginosa* with all antimicrobial agents, and staphylococci with quinolones. For *S. aureus*, vancomycin-susceptible isolates may become vancomycin intermediate during the course of prolonged therapy.

In certain circumstances, testing of subsequent isolates to detect resistance that may have developed might be warranted earlier that within three to four days. The decision to do so requires knowledge of the specific situation and the severity of the patient's condition.

Interpretation of Microbiology Reports

Semi-quantitative Terminology (rare/few/moderate/many):

The amount of each type of organism seen is quantified when reading gram stains using the following interpretive criteria:

Description	No. per oil immersion field (×1000)	
	Cells	Bacteria
Rare	<1	<1
Few	1–5	2–10
Moderate	6–10	11–50
Many	>10	>50

Of note, when a report says, “rare gram negative bacilli” it does not mean rare as in unusual, it means rare as in very few.

Contaminant vs. Pathogen:

BLOOD

Normally Sterile

PATHOGENS

- Any organism isolated

LIKELY CONTAMINANTS

- Coagulase negative staphylococci
- Alpha-hemolytic streptococci
- *Bacillus* spp.
- *Corynebacterium* spp. (except *C. jeikeium*)
- *Cutibacterium acnes (prev. Propionibacterium acnes)*

TISSUE AND BODY FLUIDS

Normally Sterile

PATHOGENS - Any organism isolated; use judgment to evaluate the possibility of normal flora being present in relation to the source of specimen.

EYE/EAR

NORMAL FLORA:

- coagulase negative Staphylococci
- Non-hemolytic streptococci
- Alpha-hemolytic streptococci
- Diphtheroids

SKIN

NORMAL FLORA:

- coagulase negative staphylococci
- *Cutibacterium acnes (prev. Propionibacterium acnes)*
- Diphtheroids
- Alpha-hemolytic streptococci
- *Bacillus* spp.

GENITAL

PATHOGENS

- *Neisseria gonorrhoeae*
- Beta-hemolytic streptococci (GBS will be held if present for susceptibility testing if needed)
- Predominant growth of Yeast or *S aureus*

URINE

Should be sterile. Cultures with mixed flora will be reported as such if contamination is suspected.

PATHOGENS

- Enterobacterales
- *Enterococcus* spp.
- *Pseudomonas* spp. and other non-fermenters
- Group B *Streptococcus* (*Streptococcus agalactiae*)
- *S. aureus* and *S. saprophyticus*
- Yeast
- *Aerococcus urinae*

STOOL (CULTURES NO LONGER PERFORMED IN-HOUSE):

ENTERIC PATHOGEN TESTING BY PCR/HYBRIDIZATION:

- *Shigella* spp.
- *Salmonella* spp.
- *Campylobacter* group (*C. coli, C. jejuni,* and *C. lari)*
- *Yersinia enterocolitica*
- *Vibrio* group (*V. cholera and V. parahaemolyticus)*
- Shiga-toxin producing strains of *E coli* (both shiga toxin 1 and 2)
- Norovirus (GI and GII)
- Rotavirus A

Note: If cultures for *Aeromonas or Plesiomonas* are needed, specific orders for these organisms will need to be requested and these specimens will be referred to the reference laboratory.

RESPIRATORY TRACT

PATHOGENS:

- Group A *Streptococcus (Streptococcus pyogenes*)
- Group C *Streptococcus* (large colony)
- Group G *Streptococcus* (large colony)
- *Arcanobacterium haemolyticum*
- *Streptococcus constellatus subsp. pharyngis*
- *Streptococcus pneumoniae*
- *Haemophilus influenzae*
- *Moraxella catarrhalis* (predominant)
- *Enterobacterales* (lower respiratory tract)
- *Pseudomonas* spp. and other non-fermenters
- *Burkholderia cepacia*
- Yeast (predominant)
- *S. aureus* (predominant)

Specimen Requirements

Specimen requirements can be found by going to the on-line LMH Lab Test Directory (link as follows): http://www.testmenu.com/lmh

Timing of Reports

Preliminary/Final Reports:
Cultures are examined each day and preliminary reports are generated on a daily basis that include any information or presumptive identification of organisms isolated that would be helpful to the physician. When the culture is completed, a final report is released.

Gram Stain:

Surgical specimens, sterile body fluids and bronch washings and brushings-within 1 hour of receipt in lab

Organism identification:

The organism will be identified within 24 hours of isolation of an organism unless it is an unusual or fastidious organism and/or requires further work-up to confirm.

Susceptibility results:

The susceptibility results will be reported within 24-48 hours of isolation of an organism unless it is an unusual or fastidious organism and/or requires further work-up to confirm identification.

Antibiogram:

The hospital-wide antibiogram can be found on the intranet by selecting resources, clinical, antimicrobial stewardship, antibiogram. It is updated every 12 months and approved by the antibiotic stewardship committee.

Urinalysis and Urine Culture

Indicators of Infection from a Urinalysis:

- Positive nitrite
- ≥5 WBC's/hpf on patients ≥60 years of age
- ≥5 WBC's/hpf and epithelial cells <16/hpf on patients <60 years of age (if it is a cath specimen, epi's don't count)

Note: A urine culture should be ordered separately for neutropenic patients with possible urinary tract infection. Urinalysis with culture if indicated is not appropriate for those patients.

Urine Culture:
A urine culture must ALWAYS be interpreted in the context of a urinalysis and patient symptoms. Ideally, a urine culture would not be performed unless a urinalysis indicated a possible infection. Typically, catheterized patients can become colonized within 48 hours of catheterization. The only patient populations for which it is recommended to screen for and treat asymptomatic bacteriuria are pregnant women and patients scheduled for genitourinary surgical procedure.

Urine cultures are held for 2 days before finalizing as "No Growth."

Guidelines for the Prevention of Perinatal Group B Streptococcal (GBS) Disease published in Nov. 2010 note that the presence of group B Streptococcus in amounts of ≥ 10,000 CFU/ml during any trimester is considered indicative of heavy maternal colonization of GBS in the vaginal flora. (i.e. Maternal GBS bacteriuria at any point during pregnancy is a recognized risk factor for early-onset GBS disease and therefore has been included as an indication for intrapartum antibiotic prophylaxis.)

If GBS is present as the predominant organism, susceptibility will be performed and reported. If susceptibility testing is not performed and the patient is female, the organism will be held for 2 weeks and the following comment is attached to the report: "Presence of group B Strep in urine samples of pregnant individuals during any trimester is indicative of heavy maternal GBS colonization if the patient is pregnant and penicillin allergic, notify the laboratory if susceptibility testing is required. Disregard if susceptibility testing was performed."

Stool Testing

Stool for WBC's: The presence of fecal leukocytes suggests inflammation of the bowel. This should lead the physician to evaluate for the cause of inflammation and consider selective cultures for the most common invasive pathogens such as: *Campylobacter* spp., *Salmonella* spp., *Shigella* spp., and enterohemorrhagic *E coli* 0157:H7.

Enteric pathogen (EP) testing: Stool cultures (in-house) were discontinued in July 2015. Testing of liquid and soft stool specimens is now performed on the Verigene Nanosphere system. This assay utilizes amplification (PCR) and hybridization to qualitatively detect and identify common gastrointestinal pathogens.

The EP assay detects and identifies the following enteric bacteria/toxins and viruses: *Campylobacter group (C. coli, C. jejuni, and C. lari), Salmonella* species, *Shigella* species, *Vibrio* group (*V. cholera* and *V. parahaemolyticus), Yersinia enterocolitica,* Shiga toxins 1 and 2 (STEC), Norovirus and Rotavirus. If the sample is positive for *Vibrio, Salmonella, Shigella* or STEC, the specimen will be sent to KDHE for further identification.

Note: This assay is FDA-approved for testing of liquid or soft stools. Testing of formed stools is not indicated.

If *Plesiomonas shigelloides or Aeromonas* spp. are suspected, separate orders are required for referral to the reference laboratory.

Note: It is inappropriate to order enteric pathogens testing on patients who have been hospitalized for more than 3 days and then develop diarrhea. In these situations, studies have shown that the most common pathogen is *C.difficile* and PCR testing should be ordered.

Stool should be tested for *Clostridioides (prev. Clostridium) difficile* on patients over 6 months of age with clinically significant diarrhea and a history of antibiotic exposure. Current College of American Pathologists (CAP) guidelines indicate that a provider should consider *C. difficile* testing as an alternative to routine microbiologic studies for inpatients over 6 months of age who have test requests for routine enteric pathogens.

Additionally, CAP clinical guidelines indicate that no more than 2 stool specimens/patient should be accepted without prior consultation with the provider who can explain the limited yield provided by additional specimens.

***Clostridioides (prev. Clostridium) difficile* testing by PCR:**

The Cepheid Gene XPert C diff/epi assay is the test currently used for diagnosing *C. difficile* infection (CDI) at LMH. This assay is a qualitative *in vitro* diagnostic test for rapid detection of toxin B gene sequences and for the presumptive identification of 027/NAP1/BI strains (epidemic, "epi"), of toxigenic *C. difficile* from unformed (liquid or soft) stool specimens collected from patients suspected of having CDI.

The test utilizes automated real-time polymerase chain reaction (PCR) to detect toxin gene sequences associated with toxin producing *C. difficile*. The assay is intended as an aid in the diagnosis of CDI.

Detection of 027/NAP1/B1 strains of *C. difficile* by the assay is presumptive and is solely for epidemiological purposes and is not intended to guide or monitor treatment for CDI. 027/NAP1/B1 strains of *C. difficile* have been referred to as "hypervirulent." These strains exhibit increased toxin production and are thought to produce more spores leading to enhanced persistence in the environment.

Testing will not be performed on formed stool (stool that does not take the shape of the container) unless a rare case of ileus is suspected. In cases of suspected ileus, a formed stool may be tested by special request of the physician.

The *C. difficile* assay should not be used to assess response to therapy. Patients can continue to test positive after treatment.

Blood Cultures

A minimum of two sets (four bottles; one set = one aerobic bottle + one anaerobic bottle) should usually be obtained. The suggested volume of blood per bottle for adults is 10 ml.

Ordering one set may lead to confusion if the culture is positive for an organism that is commonly a contaminant. For example, if one set is ordered and is positive for coagulase-negative staphylococci (CoNS), a common contaminant, it is difficult to determine if this represents contamination or infection. However, if two sets are ordered, and only one is positive for CoNS, this most likely represents contamination.

Please specify the desired sites of the blood draw (e.g., one from line, one peripherally). Ideally, blood cultures should be drawn before the first dose of antibiotics, but antibiotics should not be withheld because of a delay in getting cultures drawn. Although it is common practice to wait 30-60 minutes between blood cultures, there is little data to support this practice, and we do not recommend it.

If a vascular catheter is thought to be a potential site of infection, blood should be drawn from the catheter and the periphery. Site and time of phlebotomy should be noted. The differential time to positivity can help in assessing whether the catheter is the likely source.

Differential Time to Positivity (DTP)

a. A positive line culture result is obtained at least 2 hours earlier than a positive peripheral blood culture result.

b. Typically, the diagnosis of a line-associated infection can be made according to the following criteria: presence of an intravascular device, at least one positive blood culture obtained from a peripheral site, clinical manifestations of infection, and no other apparent source for bloodstream infection

Blood Cultures are held for 5 days prior to reporting the culture as final for no growth.

Blood cultures are continuously monitored by the BacTAlert 3D analyzer. If a positive bottle is detected, a gram stain is prepared and the bottle is sub-cultured at that time. The result of the gram stain is called to the physician immediately.

If the Gram stain indicates the presence of Gram positive cocci or bacilli, PCR testing will be performed on the GenMark analyzer for the presence or absence of targets specific for:

Streptococccus pyogenes (group A Beta *Strep*)

Streptococcus agalactiae (group B Beta *Strep*)

Streptococcus pneumoniae (*Streptococcus mitis* can cross react with *S pneumo* target)

Streptococcus anginosus group

Streptococcus species

Enterococcus faecalis

Enterococcus faecium

Listeria species

Listeria monocytogenes

Bacillus cereus group

Bacillus subtilis group

Cutibacterium acnes (prev. Propionibacterium acnes)

Lactobacillus species

Staphylococcus species

Staphylococcus aureus

Staphylococcus epidermidis

Staphylococcus lugdunensis

mecA and *mecC* for methicillin resistance in *Staph* species

vanA and *vanB* for vancomycin resistance in *Enterococcus*

The assay includes a pan Candida and pan Gram negative target to detect mixed infections, further testing would be performed if positive.

If the Gram stain indicates the presence of Gram negative bacilli (rods), micro-array testing will be performed on the GenMark analyzer for the presence or absence of targets specific for:

Acinetobacter baumannii

Bacteroides fragilis

Citrobacter species

Enterobacter cloacae complex and Enterobacter non-cloacae complex

E coli

Fusobacterium necrophorum and Fusobacterium nucleatum

Haemophilus influenzae

Klebsiella oxytoca

Klebsiella pneumoniae group

Morganella morganii

Neisseria meningitidis

Proteus species and Proteus mirabilis

Pseudomonas aeruginosa

Salmonella

Serratia and Serratia marcescens

Stenotrophomonas maltophilia

The assay includes a pan Candida and pan Gram positive target to detect mixed infections, further testing would be performed if positive.

The assay can also detect the CTX-M, KPC, NDM, OXA, IMP and VIM resistance mechanisms if an organism is detected.

If yeast are present on Gram Stain a fungal panel can be performed on the GenMark analyzer that can detect the following fungal species: *Candida albicans, Candida auris, Candida dubliniensis, Candida famata, Candida glabrata, Candida guilliermondii, Candida kefyr, Candida lusitaniae, Candida parapsilosis, Candida tropicalis, Cryptococcus gattii, Cryptococcus neoformans, Fusarium and Rhodotorula.*

Respiratory Cultures/Testing

Lower respiratory tract: Appropriate specimens to identify pathogens causing disease of the lower respiratory tract (tracheitis, bronchitis, pneumonia, lung abscess, and empyema) include expectorated and induced sputum, endotracheal tube aspirations, bronchial brushings, washes, or alveolar lavages collected during bronchoscopy and pleural fluid.

Sputum evaluations are performed on all sputum specimens using the gram stain to assess for quality (lack of contaminating oral respiratory tract flora and epithelial cells). An acceptable specimen generally yields less than 10 squamous epithelial cells per low power field. The presence of 25 or more polymorphonuclear leukocytes per low power field together with few squamous epithelial cells, implies an excellent specimen.

If the specimen is of poor quality, a comment is attached to the gram stain report, "Suggests orophapharyngeal contamination, interpret accordingly." The number of white blood cells may not always be relevant, because many patients are severely neutropenic and specimens from these patients will not show white blood cells on gram stain examination. If the specimen is from a patient (from either the ED or an inpatient floor) with a diagnosis of pneumonia and the specimen is poor quality, a new specimen may be requested.

Upper respiratory tract: Appropriate specimens to identify pathogens causing upper respiratory tract infections include samples from the nasopharynx, throat, oral ulcerations, and inflammatory material from the nasal sinuses.

Specific pathogens or normal respiratory flora are quantified in the culture report using the terms –many, -moderate, or –few.

All negative rapid strep tests for group A Strep are followed up with culture for group A, C, F, and G Beta hemolytic *Streptococcus*, *Arcanobacterium haemolyticum* and *Streptococcus constellatus ssp. pharyngis*.

***Legionella* and *S pneumo* antigen testing:** It is important to note that as an alternative to culture for *Legionella*, the laboratory offers a highly sensitive rapid EIA for the detection of *L. pneumophilia* antigen in the urine of patients suspected of having legionellosis. The laboratory offers a similar rapid EIA test for the detection of *S. pneumoniae* antigen in the urine of patients suspected of having pneumococcal pneumonia or sepsis. Note: A negative result does not rule out the possibility of infection but indicates that the antigen may be below the limits of detection for this assay.

Bordetella panel: The laboratory offers in-house qualitative testing using PCR for the detection of *Bordetella pertussis, Bordetella parapertussis/bronchiseptica, and Bordetella holmesii* from nasopharyngeal swabs in Universal Transport Media (UTM). Other specimen types have not been validated.

Mycoplasma pneumoniae and Chlamydia pneumoniae: See respiratory panel in Virology section to follow. Testing is performed as part of the Respiratory panel on the GenMark by pcr.

Genital Tract Cultures/Testing

Genital tract cultures are performed in the microbiology laboratory to determine the etiology of various clinical syndromes, including vulvovaginitis, genital ulcers, urethritis, cervicitis, endometritis, salpingitis, and ovarian abscess in females and urethritis, epididymitis, prostatitis, and genital ulcers in males.

Genital tract cultures are held for 3 days before finalizing the report.

Bacterial Vaginosis: The gram stain is the preferred method for detecting bacterial vaginosis (BV). While it is true that *Gardnerella vaginalis* (one of the prevalent organisms in BV) is easily cultured, it can be present in greater than 60% of normal patients. The presence of "clue cells" an indication of BV, can only be determined from a gram stain and culturing the anaerobic bacteria associated with BV is too costly and time-consuming, therefore the culture should not be used for the diagnosis of bacterial vaginosis.

In our laboratory graded criteria for evaluation of the gram stain is used for determining the presence or absence of suspected bacterial vaginosis. One of the following interpretations is attached to the gram stain report: "No Evidence of Bacterial Vaginosis" (Grade 1); "Intermediate for Bacterial Vaginosis" (Grade 2); or "Bacterial Vaginosis Indicated upon Smear Review." If the specimen quality was poor a comment will be attached to the report indicating "Submitted specimen does not have sufficient vaginal material to evaluate for bacterial vaginosis."

GBS screens: Our laboratory offers two separate orders for GBS screens on pregnant females at 36 to 37 weeks of gestation. STREPB is the pneumonic developed at LMH for GBS screening on non-allergic patients. STRPBS is the pneumonic developed at LMH for GBS screening on penicillin-allergic patients to ensure that if the test is positive susceptibility testing will be performed.

Chlamydia/GC testing: The laboratory offers in-house testing using real-time PCR for the detection of *Chlamydia trachomatis* (CT) and *Neisseria gonorrhoeae* (NG) from both endocervical swabs and urine specimens. A specimen adequacy control has been added to this test to detect human cells and DNA which ensures the specimen quality is acceptable.

Results are reported as Detected or Not Detected for each specific organism. An Invalid result can be due to the presence of interfering substances or it can be due to the absence of human cells or DNA.

This test should not be used for the evaluation of suspected sexual abuse or for other medico-legal indications. This assay has not been evaluated in patients less than 14 years of age. NOTE: A negative test result does not exclude the possibility of infection because test results may be affected by improper specimen collection, concurrent antibiotic therapy or the number of organisms in the specimen which may be below the sensitivity of the test.

The test takes 90 minutes to complete. Specimens collected from patients in the Emergency Department will be performed stat. Specimens received from clinics will be performed on a routine basis ensuring results in less than 24 hours Monday through Friday.

Sensitivity and specificiity of the various specimen types are as follows:

	Endocervical Swabs		Female Urine		Male Urine	
	CT	**NG**	**CT**	**NG**	**CT**	**NG**
Sensitivity	**96.0%**	**100%**	**98.1%**	**94.4%**	**98.5%**	**98.3%**
Specificity	**99.6%**	**>99.9%**	**99.8%**	**>99.9%**	**99.8%**	**99.9%**

Trichomonas vaginalis (TVPCR):

The laboratory offers in-house testing using real-time PCR for the detection of *Trichomonas vaginalis* (TV) from both endocervical swabs and urine specimens. A specimen adequacy control has been added to this test to detect human cells and DNA which ensures the specimen quality is acceptable.

Results are reported as Detected or Not Detected. An Invalid result can be due to the presence of interfering substances (such as blood or mucous) or it can be due to the absence of human cells or DNA.

This test should not be used for the evaluation of suspected sexual abuse or for other medico-legal indications.

A negative test result does not exclude the possibility of infection because test results may be affected by improper specimen collection, concurrent antibiotic therapy or the number of organisms in the specimen which may be below the sensitivity of the test.

The test takes 70 minutes to complete, however positives may come off as soon as 40 minutes. Specimens collected from patients in the Emergency Department will be performed stat. Specimens received from clinics will be performed on a routine basis ensuring results in less than 24 hours Monday through Friday.

The sensitivities and specificities of the various specimen types are as follows:

	Endocervical Swabs	Urine
	TV	**TV**
Sensitivity	**98.9%**	**98.4%**
Specificity	**98.9%**	**99.7%**

Mycobacteriology

Specimens submitted to the laboratory for acid fast culture will be sent to reference laboratory for testing. The reference laboratory will perform a culture and fluorescent stain for *Mycobacterium* spp. and will concentrate specimens as necessary.

Specimen requirements:

Sputum: Spontaneously produced sputum is the specimen of choice. A good sputum is 5-10 mls with a minimal amount of oral or nasal secretion. Three specimens (at least one must be a first morning specimen) should be submitted, refrigerated until processed, are desirable. These specimens should be collected at least 8 hours apart. Respiratory Therapy may collect an induced specimen using inhalation treatment or nebulization. See notation regarding Acid Fast Bacilli Culture and Smear with PCR for M-TB complex below.

Urine: Early morning clean-voided specimens are preferred. Specimens should be submitted daily for at least 3 days. Refrigeration prior to processing is necessary. Direct smears are not prepared on urine specimens. Pooled specimens are not desirable because of excessive dilution, higher contamination and difficulty in concentrating.

Tissue and Body Fluids: All body fluids, exudates, and tissue should be submitted in sterile containers. Large amounts are preferable. Small amounts of exudates may require moistening with sterile saline and tissues may be sent in a small amount of sterile saline.

Gastric Lavages: Optimal time for gastric lavage is early in the morning before meals. The objective of gastric lavage is to obtain sputum that may have been swallowed during the night. The specimen should be obtained at least 8 hours after the patient has eaten or taken oral drugs. The procedure should be limited to senile, non-ambulatory patients, children younger than 3 years of age, and patients who fail to produce sputum by aerosol induction. Specimens should be collected as a series of three specimens collected on separate days.

A preliminary report is received from the state within 1-2 days. A final report, if negative, is issued at 8 weeks. Positive interim reports from DNA probes may be available in 3 days. Positive culture results will take 2-4 weeks.

The patient's physician is notified immediately if any report is positive for AFB.

The reference laboratory will perform sensitivities on *M. tuberculosis* isolates only.

In July 2016, the microbiology laboratory added a new molecular test on the Cepheid Gene Xpert for the rapid detection of *Mycobacterium tuberculosis* complex (MTB) and rifampin resistance associated mutations of the rpoB gene from both raw induced or expectorated sputum specimens. This MTB/RIF assay does not differentiate between the species of MTB-complex (*M. tuberculosis, M. bovis, M. africanum, M. canettii, M. microti, M. caprae, M. pinnipedi, M. mungi,* and *M. orygis*).

This assay is intended for use with specimens from patients for whom there is clinical suspicion of TB and who have received no more than 3 days of therapy of anti-tuberculosis therapy. This test is intended as an aid in the diagnosis of pulmonary tuberculosis when used in conjunction with clinical and other laboratory findings.

A result of "MTB not detected" from two sputum specimens is highly predictive of the absence of *M. tuberculosis* complex and can be used as an aid in the decision of whether continued airborne infection isolation (AII) is warranted in patients with suspected pulmonary tuberculosis.

The test name is "AFB by PCR with culture (AFBPCR). The test takes 2.5 hours to complete. Testing will be performed on the day shift only. This assay is not FDA approved for bronchial washings (BW's) or broncho-alveolar lavage (BAL) specimens.

A negative test result does not exclude the possibility of isolating MTB-complex from the sputum sample. An un-concentrated, non-fluorescent stain will be performed in-house on any sputum with AFBPCR ordered.

Virology

Virus detection- There are four general ways in which viral infections can be detected: culture, direct viral antigen detection, serology, or nucleic acid detection.

Culture: Specimens for culture will be sent to the reference laboratory. The site of collection must be noted for the reference laboratory to perform testing. The specimen should preferably be submitted in viral transport media (a sterile container is acceptable) and delivered to the laboratory as soon as possible.

Influenza A/B and RSV by PCR: PCR testing for Influenza A, Influenza B, and RSV (subtypes A and B) is performed in-house. The specimen requirement is a nasopharyngeal swab in viral media (UTM kit). The specimen should be refrigerated if there is more than a 24 hour delay in delivery to the laboratory. The assay takes 30 minutes to perform. Testing of inpatients and ED patients for Influenza/RSV are available as a combination panel only. Note: The option to order individual tests for influenza A/B and RSV is available for outpatients only.

Rapid antigen based tests are no longer performed in the laboratory for Respiratory Syncytial Virus (RSV) and Influenza A/B. All influenza and RSV testing is performed using PCR on a nasopharyngeal swab in viral media (UTM or M4 kit).

Sars-Cov-2: Testing is available on multiple platforms for Sars-Cov-2. The specimen requirements are for nasopharyngeal swab in VTM, UTM, or M4 saline can only be used for the Diasorin and Gene xpert assays at this time).

Respiratory Pathogen Panel: The laboratory offers in-house qualitative testing using PCR for the detection of: Influenza A, Influenza A (subtype H1), Influenza A (subtype H1N1, 2009), Influenza A (subtype H3), Influenza B, Parainfluenza 1, Parainfluenza 2, Parainfluenza 3, Parainfluenza 4, RSV A, RSV B, Rhinovirus/Enterovirus, Coronavirus, SARS-CoV-2, Adenovirus, human Metapneumovirus, *Mycoplasma pneumoniae,* and *Chlamydia pneumoniae* from nasopharyngeal swabs in viral transport Media. Other specimen types have not been validated.

Results are reported as Detected or Not Detected. A specimen yielding a negative result may contain respiratory viruses or bacteria other than those included in the assay. A negative test result does not exclude the possibility of infection because test results may be affected by improper specimen collection, concurrent antibiotic therapy or the number of organisms in the specimen which may be below the sensitivity of the test.

The test takes under 2 hours to complete. Specimens collected from inpatients and patients in the Emergency Department will be performed stat. Specimens received from clinics will be performed on a routine basis ensuring results in less than 24 hours.

Rotavirus Detection: Rotavirus is a major cause of acute gastroenteritis, especially in children 6 to 24 months in age. In addition, rotavirus infections can produce severe illness as well as asymptomatic

infection in adults. The incubation period of rotavirus infection is usually one to three days, followed by gastroenteritis with an average duration of five to eight days. Virus titers in stool reach a maximum shortly after the onset of illness, then decline. Due to inadequacies in existing culture methods, human rotavirus is not routinely isolated from rotavirus-containing specimens.

The Enteric Pathogens (EP) molecular assay detects Rotavirus A in liquid or soft stool. The specimen requirement is a stool specimen in a clean container or in Cary Blair preservative.

Norovirus Detection: Noroviruses are highly contagious and cause on average 19-21 million cases of acute gastroenteritis each year ranking norovirus in the top five pathogens for enteric illnesses.

The Enteric Pathogens (EP) molecular assay detects Norovirus GI and GII in liquid or soft stool. The specimen requirement is a stool specimen in a clean container or in Cary Blair preservative.

Mycology

Specimen Collection: The ideal specimens for fungal isolation are either tissue, sterile body fluid, or blood. If a tissue specimen is to be tested for the presence of fungi, it is important that part of the specimen is sent to the microbiology laboratory **before** the specimen is fixed in formalin for histological examination. Blood to be tested for fungus should be added to a separate blood culture bottle that can be held for 30 days.

Timing of Reports: Moulds may take 3-4 weeks to grow, whereas yeasts grow rather rapidly and can usually be identified within 3-5 days. Specimens will be finalized at 4 weeks.

Susceptibility Testing: Susceptibility testing is performed only upon special request. If susceptibility testing is needed, please contact the microbiology laboratory at 505-6177. If susceptibility testing is needed for mould, a list of antifungals for testing must be specified for the reference laboratory to perform testing.

Cryptococcus Antigen Testing in CSF/serum: The laboratory offers a highly sensitive rapid lateral flow assay that can be performed on serum or CSF. This assay is more sensitive than culture, India ink, latex agglutination and enzyme immunoassay (EIA). The assay will detect antigens for *Cryptococcus* species complex (*Cryptococcus neoformans and Cryptococcus gattii*). This test is not meant to be used as a screening test for the general population. It should only be done when clinical evidence suggests the diagnosis of cryptococcal disease. Fungal culture will be performed on all CSF's submitted for cryptococcal antigen testing.

Parasitology

Ova and Parasites: An O&P test should be ordered on patients presenting with a history of chronic diarrhea (> 10 days). It is **not** appropriate to order an O&P test if the patient develops diarrhea while in the hospital. Due to the low incidence of most parasitic infections in the United States and Kansas, stool specimens for Ova and Parasite are routinely tested only for *Giardia lamblia* and *Cryptosporidium parvum* through an EIA test. However, if the patient has a travel history that includes regions of the world where parasitic infections are endemic, microscopic evaluation for ova and parasites can be ordered. Please contact the microbiology lab if this is the case (505-6177). These specimens will then be submitted to the reference lab (ARUP) for further testing.

Timing of Reports: A *Giardia/Cryptosporidium* antigen test is available every day of the week and is offered on all shifts.

Malaria Exam: Specimens submitted for malaria exam are tested using a Rapid immunochromatographic assay. Malaria smears are sent to the reference laboratory, however, malaria may be found by the hematology department from the differential smear.

Ceftazidime	1 g IV Q8 hours *CNS infections: Use 2g dose with same frequency*	30-49: <30: HD:	1 g IV Q12 hours 1 g IV Q24 hours Load with 1 g then give 1 g after each HD session
Ceftriaxone	Meningitis or CNS Infection: 2 g IV Q12 hours For all indications other than CNS: 1 g IV Q24 hours	No renal adjustments needed	
Cefuroxime **IV**	750mg-1.5g IV Q8 hours *Note: Frequency can be increased to Q6 hours for life threatening infections*	10-20: <10: HD:	750 mg IV Q12 hours 750 mg IV Q24 hours 750 mg IV after each dialysis session
Cefuroxime **PO** tab	250-500 mg PO Q12 hours	<10:	250-500 mg Q24 hours

	Note: tablet dosing not equivalent to suspension, we do not carry suspension	HD:	250-500 mg PO q24 hours schedule dost to be given after dialysis
Cephalexin	500 mg PO Q6 hours	10-30: <10: HD:	500 mg PO Q8 hours 500 mg PO Q12 hours 250-500 mg PO q24 hours schedule dost to be given after dialysis
Ciprofloxacin **IV**	400 mg IV Q12 hours HAP or VAP: 400 mg IV Q8 hours	<30 HD:	200-400 mg IV Q24 hours 200 mg IV Q24 hours schedule dose to be given after dialysis
ANTI-INFECTIVE	**NORMAL DOSE**	**CRCL in ml/min**	**RENAL DOSE ADJUSTMENTS**
Ciprofloxacin **PO**	500 mg PO Q12 hours	10-29: <10: HD:	250 mg PO Q12 hours 250 mg PO Q24 hours 250 mg PO Q24 hours schedule dose to be given after dialysis
Clarithromycin	500 mg PO Q12 hours	10-29: <10: HD:	250 mg PO Q12 hours 250 mg PO Q24 hours 250 mg PO Q24 hours schedule dose to be given after dialysis
Clindamycin **IV**	600 mg IV Q8 hours, 900 mg IV Q8 hours for necrotizing faciitis *Note: For patients >100 kg 900 mg IV Q8 hours may be used*	No renal adjustment needed	
Clindamycin **PO**	150-450 mg PO q6-8 hours (varies by indication, please use appropriate reference)	*Note: For patients >100 kg 450 mg PO Q6 hours may be used*	
Daptomycin	4-6 mg/kg IV Q24 hours *Note: Not to be used for infections in the lungs; 4 mg/kg for UTI/SSSTI*	<30: HD:	4-6 mg/kg IV Q48 hours 4-6 mg/kg IV Q48 hours schedule dose to be given after dialysis
Dicloxacillin	125-500mg PO Q6 hours	No adjustment needed	
Doxycycline **IV** or **PO**	100mg Q12 hours	No adjustment needed	
Ertapenem	1000 mg IV Q24 hours	<30:	500 mg IV Q24 hours

		HD:	500 mg IV Q24 hours schedule dose to be given after dialysis
Erythromycin **IV**	500-1000 mg IV Q6 hours	<10:	50% PO/IV dose at same interval
Erythromycin **PO**	Base: 250-500mg PO Q6-12 h EES: 400-800mg PO Q6-12 h	HD/CAPD:	Dose the same as CrCl <10 ml/min

ANTI-INFECTIVE	**NORMAL DOSE**	**CRCL in ml/min**	**RENAL DOSE ADJUSTMENTS**
Ethambutol	Initial: 15 mg/kg PO Q24 hrs Retreatment: 25 mg/kg PO Q24 hours x 60 days, then 15 mg/kg/day *Note: Should not be used alone; Monthly eye exams recommended on high dose regimen; max dose 2.5 gm*	***** 10-50: <10: HD: ***** 10-50: <10: HD:	Initial Treatment: 15 mg/kg PO Q24-36 hours 15 mg/kg PO Q48 hours Administer dose after dialysis Retreatment: 25 mg/kg PO Q24-36 hours 25 mg/kg PO Q48 hours Administer dose after dialysis
Famciclovir	250-500 mg PO Q8 hours 500 mg PO Q8 hours for VZV *Note: no clear adjustment recommendations in CAPD*	40-59: 20-39: <20: HD:	same dose Q12 hours same dose Q24 hours 50% dose Q24 hours 50% after each dialysis session
Fidaxomicin	200 mg PO Q12 hours	No adjustment needed	
Fluconazole IV or PO	*Invasive candidiasis: 800 mg (12 mg/kg) load x1, then 400 mg (6 mg/kg) PO/IV Q24 hours	10-29: <10: HD: CAPD:	Load x1, then 50% PO/IV dose Q24 hours Load x1, then 25% PO/IV dose Q24 hours Load x1, then 400 mg (6 mg/kg) after HD 3x/weekly 50% PO/IV Q24 hours
	*Esophageal/oropharyngeal candidiasis: 200 mg PO/IV	<30:	50% PO/IV Q 24 hours

	Q24 hours for esophageal; 100 mg Q24 hours for oropharyngeal *Note: Some indications may require different dosing, please refer to appropriate drug reference*	HD: CAPD:	100% PO/IV after each dialysis session 50% PO/IV Q24 hours
Fosfomycin **PO**	Uncomplicated cystitis: 3 gm x1 Complicated cystitis: 3 gm Q48 hours	<50: <50:	Same dose 3 gm Q72 hours
ANTI-INFECTIVE	**NORMAL DOSE**	**CRCL in ml/min**	**RENAL DOSE ADJUSTMENTS**
Ganciclovir **IV**	Induction: 5 mg/kg IV Q12 hours Maintenance: 5 mg/kg IV Q24 hours	***** 50-69: 25-49: 10-24: <10: HD: ***** 50-69: 25-49: 10-24: <10: HD:	**Induction:** 2.5 mg/kg IV Q12 hours 2.5 mg/kg IV Q24 hours 1.25 mg/kg IV Q24 hours 1.25 mg/kg IV 3 x week 1.25 mg/kg IV 3 x week schedule dose to be given after hemodialysis **Maintenance:** 2.5 mg/kg IV Q24 hours 1.25 mg/kg IV Q24 hours 0.625 mg/kg IV Q24 hours 0.625 mg/kg IV 3 x week 0.625 mg/kg IV 3 x week schedule dose to be given after hemodialysis
Ganciclovir **PO**	1000 mg PO Q8 hours	50-69: 25-49: 10-24: <10 HD:	1500 mg PO Q24h or 500 mg PO Q8h 1000 mg PO Q24h or 500 mg PO Q12h 500 mg PO Q24 hours 500 mg PO 3 x week 500 mg PO 3 x week schedule dose to be given afer hemodialysis

Gentamicin *Note: Consultation with Pharmacy recommended* *Exclusion to Extended Interval: Pregnancy, breastfeeding, burns (>20% body), ascites, Enterococcoal endocarditis, HD or CrCl < 20 ml/min*	Extended Interval Dosing: 7 mg/kg IV Q24 hours *Note: draw level 6-14 hours after 1st dose* Conventional Dosing: 1-2.5 mg/kg/dose Q8 hours *Note: Peak & trough levels monitored, consult pharmacy*	***** 40-59: 30-39: <30 ***** 40-60: 20-39: <20: HD:	**Extended Interval Dosing:** 7 mg/kg IV Q36 hours 7 mg/kg IV Q48 hours AVOID, use conventional dosing **Conventional Dosing:** 1-2.5 mg/kg Q12 hours 1-2.5 mg/kg Q24 hours 1-2.5 mg/kg then monitor level 2-3 mg/kg Q48-72h, monitor level prior to HD to determine dosing needs
ANTI-INFECTIVE	**NORMAL DOSE**	**CRCL in ml/min**	**RENAL DOSE ADJUSTMENTS**
Imipenem/ Cilastatin	250-1000mg IV Q6-8 hours Usually 500 mg IV Q6 hours *Note: max dose 50mg/kg/day or 4g/day* *Note: Dose varies by severity of infection & organism sensitivity*	30-70: 20-30: 6-20: <5: HD:	Decrease daily dose by 50% & divide Q6-8 hours (round to nearest 250 mg) Decrease daily dose by 63% & divide q8-12 hours (round to nearest 250 mg) Decrease daily dose by 75% & divide Q12 hours (round to nearest 250 mg) Not recommended unless HD being started Decrease daily dose by 75% & divide q12 hours (round to nearest 250 mg); dose after dialysis on dialysis day
Isoniazid	300 mg PO Q24 hours (5 mg/kg PO Q24 hours); max of 300 mg; HD/CAPD: dose after dialysis		
Itraconazole	200 mg PO Q8-24 hours (histo/cocci/blasto: load with 200 mg Q8 hours x2 days, then 200 mg Q12 hours) *Notes: avoid PPIs/H2 blockers; suspension on empty stomach; capsules with meal or acidic drink; consider monitoring SS trough after 5-7 days (>1 mg/dL, sum of itraconzole and hydroxy-itraconazole)*		
Ketoconazole	200-400 mg PO Q24 hours Note: Dose and frequency vary by indications. Please see appropriate drug information reference.		

Levofloxacin IV or PO	Pneumonia/Pseudomonas: 750 mg Q24 hours Other Indications: 500 mg Q24 hours	20-49: 10-19: <10: HD:	Pneumonia /Pseudomonas: 750mg Q48 hours Other: 500 mg load then 250 mg Q24h Pneumonia /Pseudomonas: 500 mg Q48 hours Other: 500 mg load then 250 mg Q48h Pneumonia /Pseudomonas: 250-500 mg Q48h Other: 250 mg Q48 hours Pneumonia /Pseudomonas: 250-500 mg Q48h Other: 250 mg Q48 hours
ANTI-INFECTIVE	**NORMAL DOSE**	**CRCL in ml/min**	**RENAL DOSE ADJUSTMENTS**
Linezolid IV or PO	600 mg Q12 hours	No adjustment needed	
Meropenem	500 mg IV Q6 hours UTI: 500 mg Q8 hours Meningitis, CF, meropenem MIC of 4 mg/dL: 2 gm Q8 hours	25-49: 10-24: <10/HD: HD/CAPD	500 mg IV Q8 hours (UTI: 500 mg Q12 hours; meningitis, etc: 2 gm Q 12 hours) 500 mg IV Q12 hours (UTI: 250 mg Q12 hours; meningitis, etc: 1 gm Q12 hours) 500 mg IV Q24 hours (UTI: 500 mg Q24 hours; meningitis, etc: 1 gm Q24 hours) dose as CrCl <10, given after dialysis on dialysis days
Metronidazole IV or PO	500 mg Q12 hours if C difficile is not suspected 500 mg Q8 hours if C difficile is suspected	<10: HD/CAPD	Consider 50% at same interval if >14 day duration Give after dialysis on dialysis days
Micafungin IV	100 mg IV Q24 hours	No adjustment needed	
Minocycline **PO**	100 mg PO Q12 hours	<10: HD:	100 mg Q24 hours 100 mg Q24 hours

Nafcillin	Continuous Infusion: 8-12 g/day *Note: 12 g/day recommended for endocarditis* Intermittent Dosing: 2 g IV Q4-6 hours		No adjustment needed
Nitrofurantoin	100 mg PO Q12 hours	<60, HD/CAPD:	*<50, HD/CAPD: Use is not recommended - will not reliably reach useful concentrations in urine and will have increased risk of toxicity.*
ANTI-INFECTIVE	**NORMAL DOSE**	**CRCL in ml/min**	**RENAL DOSE ADJUSTMENTS**
Oseltamivir	Treatment: 75 mg PO Q12 hours Prophylaxis: 75 mg PO Q24 hours	<30: HD:	Prophylaxis: 75 mg PO Q48 hours Treatment/Prophylaxis: 30 mg PO x 1 before HD then after every other dialysis session x 3 doses
Penicillin G **IV**	Continuous Infusion: 18-24 million units/day Intermittent Dosing: 2-3 million units IV Q4-6 hours *Note: Doses varies by indication. Please refer to appropriate drug reference.*	***** 10-50: <10 HD: CAPD: ***** 10-50: <10:	**Continuous Infusion** 12-18 million units/day (75% IV at same time interval) 6-12 million units/day (75% IV at same time interval) Dose as CrCl <10, given after dialysis on dialysis days Dose a CrCl <10. **Intermittent Dosing** 1-2 million units/day IV Q4-6 hours 1 million units/day IV Q6 hours

Penicillin VK **PO**	500 mg PO Q6 hours *Note: Doses varies by indication. Please refer to appropriate drug reference.*	10-50: <10: HD:	500 mg PO Q8 hours 500 mg PO Q12 hours Give dose after dialysis on dialysis days
Piperacillin/ Tazobactam	Pneumonia/Pseudomonas: 4.5 g IV Q6 hours Other Indications: 3.375 g IV Q6 hours or 4.5 g IV Q8 hours	20-39: <20: HD: CAPD:	Pna/Pseudomonas: 3.375 g IV Q6 hours Other: 2.25 g IV Q6 hours Pna/Pseudomonas: 2.25 g IV Q6 hours Other: 2.25 g IV Q8 hours Pna/Pseudomonas: 2.25 g IV Q8 hours Other: 2.25 g IV Q8 hours Supplement Dose after HD: 0.75g Dose as CrCl< 20
ANTI-INFECTIVE	**NORMAL DOSE**	**CRCL in ml/min**	**RENAL DOSE ADJUSTMENTS**
Quinipristin/ Dalfopristin	7.5 mg/kg IV Q8-12 hours *Note: Synercid should be used with discretion due to cost and to maintain susceptibility profile*		
Rifampin	Doses vary by indication. Please refer to appropriate drug information reference. *Note: Should not be used alone; screen for drug interactions*		
Rimantadine	100mg PO Q12 hours	<30:	100 mg PO Q24 hours
Terbinafine	500 mg PO Q12 hours 250 mg PO Q24 hours	<50:	Use not recommended
Ticarcillin/ Clavulanate	Severe or Pseudomonas: 3.1 g IV Q4 hours Moderate: 3.1 g IV Q6 hours UTI: 3.1 g IV Q6-8 hours *Note: <60kg dose 200-300mg/kg/day divided q4-6 h*	30-60: 10-30: <10: HD: CAPD:	3.1 g IV Q8 hours 3.1 g IV Q12 hours 2 g (ticarcillin) IV Q12 hours <10 & hepatic dysf: 2 g (ticarcillin) IV Q24 hours 2 g (ticarcillin) IV Q12 hours plus 3.1 g after HD session Dose as CrCl <10.
Tobramycin	Extended Interval Dosing: 7 mg/kg IV Q24 hours	***** 40-59: 30-39:	**Extended Interval Dosing:** **Frequency determined by levels/Hartford nomogram** 7 mg/kg IV Q36 hours 7 mg/kg IV Q48 hours

Note: Consultation with Pharmacy recommended.	*Note: draw level 6-14 hours after 1st dose* Conventional Dosing: 1-2.5 mg/kg/dose Q8 hours *Note: Peak & trough levels monitored, consult pharmacy*	<30 ***** 40-60: 20-39: 10-20: <10: HD:	AVOID, use conventional dosing **Conventional Dosing (empiric, before levels):** 1-2.5 mg/kg Q12 hours 1-2.5 mg/kg Q24 hours 1-2.5 mg/kg Q48 hours 1-2.5 mg/kg Q72 hours 2-3 mg/kg Q48-72h, monitor level prior to HD to determine dosing needs
ANTI-INFECTIVE	**NORMAL DOSE**	**CRCL in ml/min**	**RENAL DOSE ADJUSTMENTS**
Trimethoprim/ Sulfamethoxazole **PO** (1 Bactrim DS tablet = 160mg(TMP)/800(SMX) *Note: When changing from IV to PO use the same trimethoprim dose as IV*	MRSA cellulitis (or Skin/skin structure infection/other infections): 1-2 DS tablets Q12 hours Other Indications: 1 DS tablet Q12 hours	15-30: <15: HD:	Increase interval to Q24 hours or Decrease dose by 50% (ie. DS to SS) AVOID or decrease dose 50% (ie. DS to SS) <u>AND</u> increase interval to Q48 hours Dose according to dosage for <15, schedule dose to be given after dialysis
Trimethoprim/ Sulfamethoxazole **IV** *Note: Dosing is based on Trimethoprim component*	<u>Pneumocystis treatment:</u> 15-20 mg/kg/day in 3-4 divided doses <u>Severe Infections:</u> 8-10 mg/kg/day in 2-4 divided doses	15-30 <15	50% of usual dose in 2-4 divided doses AVOID if possible ***Pneumocystis treatment:*** 15-20 mg/kg/dose Q48 hours or 7-10 mg/kg/day divided in 1-2 doses ***Severe Infections:***

			8-10 mg/kg/dose Q48 hous or 4-5 mg/kg/day divided in 1-2 doses
		HD:	Dose according to dosage for <15, schedule dose to be given after dialysis
ANTI-INFECTIVE	**NORMAL DOSE**	**CRCL in ml/min**	**RENAL DOSE ADJUSTMENTS**
Vancomycin *Note: Consultation with Pharmacy recommended.*	Loading Dose: 20 mg/kg IV x 1 Maintenance: 15-20 mg/kg IV Q8-12 hours Max Dose 2000 mg Round to nearest 250 mg *Note: trough levels should be monitored on patient with expected duration > 3 days*	40-60: 25-39: <24: HD:	15-20 mg/kg IV Q24 hours 15-20 mg/kg IV Q48 hours Dosing adjustments per levels Dosing adjustments per levels
*Dosing, therapeutic goals, and monitoring should be individualized for each patient. Troughs of 15-20 mcg/mL are recommended for patients with MRSA bloodstream infections, endocarditis, meningitis, pneumonia, osteomyelitis, and septic arthritis.			
Valacyclovir	250-500 mg PO Q8 hours *Note: Dose and frequency vary by indications. Please see appropriate drug information reference.*		*Note: Renal dose adjustments vary by indication, please refer to appropriate drug reference*
	2g PO q12h	30-49: 10-29: <10:	1g PO q12h 1g PO q12h 500mg PO q24h

	1g PO q8h	30-49: 10-29: <10:	1g PO q12h 1g PO q24h 500mg PO q24h
