#### **Opioid Notes**

Opioids undergo phase I metabolism by the CYP pathway, phase II metabolism by conjugation, or both. Phase I metabolism of opioids primarily involves CYP3A4 and CYP2D6 enzymes. Drug-drug interactions may occur when opioids are used concurrently with inducers or inhibitors of CYP enzymatic pathways. Morphine, oxymorphone, and hydromorphone undergo phase II glucuronidation, and their glucuronide forms are directly detected by this assay.

Unlike immunoassays, the LC-MS/MS method can identify both parent compounds and their metabolites. Historically patient chronic opioid therapy (COT) non-adherence may have been presumed if both parent compound and metabolite were not present. However, more recently published evidence has demonstrated that in some cases only the metabolite may be present with no evidence of parent medication. In other cases, only high levels of the parent medication are present with little to no metabolite.

Approximately 7-10% of Caucasians lack an active CYP2D6 enzyme and are unable to metabolize codeine to morphine. Metabolism of codeine can also be impacted due to the influence of CYP2D6 inhibitors, including Paxil® or Wellbutrin®.

Hydromorphone is a minor metabolite of morphine, and its concentration rarely exceeds 2% of urine morphine concentration in patients taking morphine<sup>3</sup>.

For patients prescribed Suboxone® a metabolite-to-parent drug ratio of about 4.52 is expected<sup>3</sup>.

For patients prescribed methadone a ratio of methadone to EDDP (inactive metabolite) of about 1:1 is expected in urine<sup>3</sup>, although absolute concentrations found in a given urine sample may be highly variable. Urinary excretion of methadone decreases with increasing urine pH.

The presence of 6-acetylmorphine (6-MAM) is conclusive evidence of prior heroin use. Because half-life for 6-MAM is short, it may be detected in urine only up to 8 hours after administration. Morphine or its metabolites may be the only compound(s) detected following heroin use. Illicit heroin frequently contains small amounts of acetylcodeine, which is further metabolized to codeine. The presence of both codeine and morphine in urine does not rule out the use of heroin.
